Abstract

An experimental study was conducted in the Langley Transonic Dynamics Tunnel to investigate the use of a Bell Helicopter Textron rotor structural tailoring concept, known as rotor nodalization, in conjunction with advanced blade aerodynamics, and to evaluate rotor-blade aerodynamic design methodologies. A 1/5-size, four-bladed bearingless hub, three sets of Mach scaled model rotor blades, and two sets of Froude scaled model rotor blades were tested in forward flight from transition up to an advance ratio of 0.35. The data presented herein pertain only to evaluation of the structural tailoring concept and consist of fixed-system and rotating-system vibratory loads. These data are useful for evaluating the effects of tailoring blade structural properties on fixed-system vibratory loads and for validating analyses used in the design of advanced rotor systems.

Introduction

Vibration has always been a problem for all helicopters. Excessive vibration levels have adverse effects on crew members, passengers, and aircraft components. Decreased vibration levels reduce crew fatigue and discomfort, increase aircraft component reliability, and reduce aircraft maintenance costs. To obtain these desired benefits, helicopter manufacturers have initiated research programs with the aim of reducing excessive vibrations.

The rotor system, which transmits the vibratory air loads to the fuselage through the rotor shaft, is one of the most significant contributors to the vibrations of the helicopter. As the loads from the individual blades combine at the rotor hub, some harmonics cancel each other, and others are additive. The additive loads are passed from the blades to the rotor shaft and then to the fuselage. These loads are felt as vibratory forces and moments whose frequencies are integer multiples of the blade passage frequency (number of blades times rotational frequency).

Various mechanical devices (e.g., absorbers, isolators) and aerodynamic techniques, such as higher harmonic control, have been proposed to either isolate or cancel these undesirable dynamic loadings and thus prevent their transmission through the shaft (ref. 1). However, these devices have the disadvantages of significant weight penalty, added parts, increased maintenance requirements, and possible degradation of rotor performance. Vibration reduction may be better achieved by structural tailoring of the rotor; this method has the advantage of addressing the vibration problem in the design stage. Generally, a structurally tailored rotor is one in which mass

and stiffness may be varied to tune rotor modes that may result in lower airframe vibration. Analytical investigations (refs. 2 and 3) have predicted that significant reductions in rotor vibratory loads may be obtained with structurally tailored rotors.

To experimentally evaluate a Bell Helicopter Textron rotor structural tailoring concept, known as rotor nodalization (refs. 4 and 5), a study was conducted in the Langley Transonic Dynamics Tunnel. The objective of a nodalized rotor design is cancellation of inertial and aerodynamic loads at the rotor hub at a frequency equal to the blade passage frequency (ref. 5). This study was a part of ongoing programs of the U.S. Army and NASA to improve the aerodynamic performance of helicopters and to reduce helicopter vibrations (refs. 6 to 10). The objective of the study was to investigate the use of structural tailoring in conjunction with advanced blade aerodynamics and to evaluate rotor-blade aerodynamic design methodologies. The data presented herein pertain only to evaluation of the structural tailoring concept and consist of fixed-system and rotating-system vibratory loads measured in forward flight from transition to high speed. The purpose of this report is to present these data for use in analytical correlations.

Symbols

The positive directions of forces, angles, and velocities are shown in figure 1.

A	balance axial force, positive downstream perpendicular to rotor shaft, lb
D	rotor drag, lb, $N \sin \alpha_s + A \cos \alpha_s$
EIB	blade beamwise stiffness, lb-in ²
EIC	blade chordwise stiffness, lb-in ²
f _D	vehicle equivalent parasite area, ft ²
GJ	blade torsional stiffness, lb-in ²
IB	blade beamwise cross-section mass moment of inertia per unit length, in-lb-sec ² /in.
IC	blade chordwise cross-section mass moment of inertia per unit length, in-lb-sec ² /in.
L	rotor lift, lb, $N \cos \alpha_s - A \sin \alpha_s$
MAG	magnitude
N	balance normal force, positive upward along rotor shaft, lb

nP	n th harmonic of rotor rotational frequency
Q	rotor-shaft torque, measured from balance yawing-moment channel, in-lb
R	rotor radius, in.
r	spanwise distance along rotor radius measured from center of rotation, in.
Sta.	blade radial station measured from center of rotation, in.
V	free-stream velocity, ft/sec
XCG	chordwise location of blade center of gravity measured from inboard leading edge, positive aft, in.
XNA	chordwise location of blade tension axis measured from inboard leading edge, positive aft, in.
α_s	rotor-shaft angle of attack, positive for rotor shaft tilted aft, deg (AlphaS in computer generated data tables)
μ	rotor advance ratio, $V/\Omega R$ (Mu in computer generated data tables)
ρ	mass density of test medium, slugs/ ft^3
ψ	rotor-blade azimuth angle, deg
Ω	rotor rotational velocity, rev/min

Apparatus and Procedures

Wind Tunnel

The testing was conducted in the Langley Transonic Dynamics Tunnel (TDT). A schematic of the tunnel is shown in figure 2. The TDT is a continuous-flow tunnel with a slotted test section and is capable of operation up to Mach 1.2 at stagnation pressures from near vacuum up to 1 atm. The tunnel test section is 16 ft square with cropped corners and has a cross-section area of 248 ft^2 . Either air or a heavy gas, dichlorodifluoromethane (R-12), may be used as the test medium. For this investigation, both air and R-12 were used. The testing in air was conducted at atmospheric pressure at a nominal density of 0.00238 slug/ ft^3 , and the testing in R-12 was conducted at less than atmospheric pressure at a nominal density of 0.006 slug/ ft^3 . Because of its high density and low speed of sound, the use of R-12 aids

the matching of model-rotor-scale Reynolds number and Mach number to full-scale values. The use of R-12 as a test medium also allows the easing of some restrictions on model structural design while maintaining dynamic similarity. For example, a heavier test medium permits a simplified structural design to obtain the required stiffness characteristics, and thus eases design and fabrication requirements of the model (ref. 11).

Model Description

Rotor hub. The model rotor hub used in this investigation was a 1/5-size, four-bladed bearingless hub (fig. 3). Rotor flap, lag, and pitch motions are accommodated by flexural arms that are constructed of fiberglass, extend outward from the centerline, and are pre-coned 2.75° upward at their inboard end. The hub is formed by the two flexural members; each continues across the shaft attachment and is connected to grips for opposite blade pairs. The members are stacked vertically and are bolted to the mast at their centers. From the center of rotation, each flexural arm structurally transitions into a flat flapping element and then into a torsionally soft feathering element with a cruciform cross section. Blade lead-lag motion occurs as a result of flexibility in the cruciform cross section. The cruciform shape ends in a built-up area that contains the bushings for attachment of the cuffs. A torsionally stiff cuff encompasses each flexure. The cuff, used to control blade feathering, is bolted to the grip at its outboard end and is shear restrained to the flexure at its inboard end. The shear restraint mechanism is pinned at $r = 2.4$ to allow motion in the pitch direction and contains elastomeric shear pads that provide inplane damping augmentation. To assure that there were no aeromechanical instabilities during testing, shear pads of three different stiffnesses were used. Small shear pads were used during the air testing of the Froude scaled blades, and medium and large shear pads were used during testing of the Mach scaled blades in R-12. The trailing-edge pitch horn is attached to the inboard end of the cuff. Pitch-link loads introduced to the horn will be reacted at the shear restraint in such a way as to generate a torsional couple, so the cuff will be rotated and the attached flexure will be twisted. The shear restraint rotates in pitch with the cuff and blade.

Rotor Blades. Five sets of 1/5-size, model blades designed to represent those of an intermediate-weight civil helicopter were used during these tests. A general description of the characteristics and designation of each blade set is presented in table I. The

two sets of Froude scaled blades identified as -100 and -200 in table I were tested in air at $\rho = 0.00238$ slug/ft³. The three sets of Mach scaled blades identified as -300, -400, and -500 in table I were tested in R-12 at $\rho = 0.006$ slug/ft³. The blades tested in air were used to evaluate structural tailoring, while the blades tested in R-12 were used to evaluate the use of structural tailoring in conjunction with advanced blade aerodynamics.

The -100 blades (fig. 4) were used as the baseline blades for the air testing and were constructed using an aluminum spar of rectangular cross section. The structurally tailored -200 blades (fig. 4) were constructed by using an aluminum spar with an I-beam cross section. The inboard end of the spar has weight pockets that accommodate nonstructural mass from $r/R = 0.31$ to $r/R = 0.43$. Both the -100 and -200 blade sets use a cellular foam construction to achieve the NACA 0012 airfoil shape (table I). The calculated structural properties of the -100 and -200 blades are presented in tables II and III and in figures 5 to 8.

The -400 and -500 blades each have the same aerodynamic design, which is different from the aerodynamic design of the -300 blades. There were differences in the aerodynamic designs so that the aerodynamic design methodology could be evaluated. The results of the evaluation of the aerodynamic design methodology are neither presented nor discussed in this report. The -300 blades were structurally tailored, had a thrust-weighted solidity of 0.079, and, as indicated in table I and figure 9, used multiple airfoils. The SFN2322 airfoil is 22 percent thick and was used only at the root end of the blade. Versions of the SFN2322 with reduced thickness were used to transition to the 10-percent-thick SFN8010 airfoil at $r/R = 0.45$. The SFN8010 airfoil was used from $r/R = 0.45$ to $r/R = 0.80$ and is the same as the RC(4)-10 airfoil (ref. 12) except for a slight modification to the lower surface near the airfoil trailing edge. Versions of the SFN8010 with reduced thickness were used to transition to the 8-percent-thick SFN9508 airfoil at $r/R = 0.95$. The 6-percent-thick SFN10006 airfoil was used only at the blade tip. The -400 blades were structurally tailored; as indicated in table I and figure 9, the -400 and -500 blades were tapered in planform with a 3:1 taper ratio beginning at $r/R = 0.60$, and each used three advanced airfoil sections. The RC(4)-10 airfoil was used in the inboard region of each blade from $r/R = 0.275$ to $r/R = 0.80$, the RC(3)-10 airfoil was used from $r/R = 0.85$ to $r/R = 0.90$, and the RC(3)-08 airfoil (ref. 13) was used in the tip region of each blade from $r/R = 0.95$ to $r/R = 1.0$. Smooth transitions were

made over the 5 percent of blade radius between the different airfoil sections. The area, thrust-weighted, and torque-weighted solidities of the -400 and -500 blades were 0.081, 0.079, and 0.073, respectively. The calculated structural properties of the -300, -400, and -500 blades are given in tables IV to VI and figures 10 to 13.

Aeroelastic rotor experimental system.

Each blade set was tested using the aeroelastic rotor experimental system (ARES) model shown in figures 14 and 15. The ARES model has a streamlined fuselage shape which encloses the rotor controls and drive system. The ARES model is powered by a variable-frequency synchronous motor rated at 47-hp output at 12 000 rpm. The motor is connected to the rotor shaft through a belt-driven two-stage speed reduction system. The ARES model rotor control system and rotor-shaft angle of attack α_s are remotely controlled from the wind-tunnel control room. The model rotor-shaft angle of attack is varied by an electrically controlled hydraulic actuator. Blade collective pitch and lateral and longitudinal cyclic pitch are input to the rotor through the swash plate. The swash plate is moved by three electrically controlled hydraulic actuators.

Instrumentation mounted on the ARES model allows continuous displays of model control settings, rotor forces and moments, blade loads, and pitch-link loads. For these tests, one pitch link was instrumented with a strain gage to measure pitch-link tension and compression loads. The pitch-link loads were monitored during testing for safety of flight information and are not presented in this report. Rotor-blade flap and lag motions were determined from strain gages mounted on one flexure of the rotor hub. Rotor-shaft speed was determined by a magnetic sensor. Strain-gage data from the rotating system were transferred to the fixed system through a 30-channel slip-ring assembly. Rotor forces and moments were measured by a six-component strain-gage balance mounted below the drive system. Rotor lift and drag were determined from the measured balance normal and axial forces. Rotor torque was measured by the balance yawing-moment channel. The balance was fixed with respect to the rotor-shaft axis and pitched with the fuselage. Fuselage aerodynamic forces and moments were not sensed by the balance.

Test Procedure

Because the purpose of this test was to obtain data to evaluate the effects of structural tailoring on fixed-system vibratory loads, each blade set was evaluated at the same nominal test conditions defined

by μ , Ω , L , and D . The value of Ω used for all test points was 780 rpm. The values of L and D for all five sets of blades tested were chosen to represent an aircraft of 7850 lb gross weight and an equivalent parasite area of 20.65 ft² operating at a density altitude of 4000 ft and 95°F. Simulated values of rotor drag were determined at each value of μ as follows: $D = f_D(1/2\rho V^2)$. The values of L and D were then used to determine α_s . The range of μ covered in these tests was from transition to high speed ($\mu = 0.060$ to 0.35). However, for the -300 and -400 blades tested in R-12, the maximum value of μ for which data were obtained was 0.30 as a result of excessive rotor loads. At each test point, the rotor rotational speed and tunnel conditions were adjusted to give the desired values of Ω and μ . Model α_s and model L were then adjusted to the desired values. To facilitate data acquisition and reduce blade loads, rotor cyclic pitch was used to remove rotor first-harmonic flapping with respect to the rotor shaft at each test point. At most test conditions, at least two data points were taken to quantify any scatter in the measurements. The maximum obtainable values of μ and α_s were constrained by either hub and blade load limits or ARES model drive-system limits. Since the purpose of this report is to present rotating and fixed-system vibratory loads, neither model deadweight tares nor balance interactions have been applied to the data. The tares and interactions were not applied, because they affect only the mean value of each measurement, not the vibratory content.

Results

Data obtained during this investigation consist of fixed-system vibratory loads data, measured by the ARES strain-gage balance, and rotating-system data, determined from strain gages mounted on the rotor hub at $r = 1.4$ and 3.0. These data are presented in tables VII to XII. Data are not presented at all test conditions for the rotor-hub instrumentation because of strain-gage failures. For each blade set tested, the data from each balance and hub strain-gage channel are presented in the tables, along with the corresponding values of Mu (μ) and AlphaS (α_s). Each data point is identified by a specific test-point number. The data presented consist of the mean value and the first eight harmonic components of a Fourier analysis of the output of each data channel. The units of the mean and the magnitude of each harmonic component are pounds and inch-pounds as appropriate, and the phase angle of each harmonic component is measured in degrees referenced in the direction of rotor rotation from 0° over the tail of the model. Because the rotors tested were four-bladed

rotors, the harmonics of importance for evaluating the effects of structural tailoring are the 3P and 5P rotating-system hub bending moments and the 4P fixed-system forces and moments. A review of the data presented in the tables indicates that the data scatter for the important fixed-system and rotating-system harmonics is within reasonable bounds.

The data for the -100 and -200 blades (small shear pads) are presented in tables VII and VIII; the data for the -300 and -400 blades (medium shear pads) are presented in tables IX and X; and the data for the -400 and -500 blades (large shear pads) are presented in tables XI and XII.

Concluding Remarks

Fixed-system and rotating-system vibratory loads data have been obtained for a bearingless rotor model in forward flight. These data are useful for evaluating the effects of tailoring blade structural properties on fixed-system vibratory loads and validating analyses used in the design of advanced rotor systems.

16. Abstract An experimental study was conducted in the Langley Transonic Dynamics Tunnel to investigate the use of a Bell Helicopter Textron rotor structural tailoring concept, known as rotor nodalization, in conjunction with advanced blade aerodynamics, and to evaluate rotor-blade aerodynamic design methodologies. A 1/5-size, four-bladed bearingless hub, three sets of Mach scaled model rotor blades, and two sets of Froude scaled model rotor blades were tested in forward flight from transition up to an advance ratio of 0.35. The data presented herein pertain only to evaluation of the structural tailoring concept and consist of fixed-system and rotating-system vibratory loads. These data are useful for evaluating the effects of tailoring blade structural properties on fixed-system vibratory loads and for validating analyses used in the design of advanced rotor systems.
